DUNDEE APPLE SAUCE
7 303 Cans **99¢**

HUDSON HOUSE LEAF SPINACH
7 303 Cans **99¢**

Scientists Get Look At Cancer In Nature's Mice

By DELOS SMITH
UPI Science Editor

NEW YORK (UPI) — For the first time cancer research has had a very close look at what cancer does to nature's own mice — the mice housewives may have a chance to shriek at and which may be living right now in your cellar.

A large amount of cancer research is done in mice but these mice are science's animals rather than nature's. They've been selectively bred, cross-bred and inbred over hundreds of mouse generations, in ways that couldn't possibly happen naturally.

In their hereditary chemistry nature couldn't recognize some of these lines as mice. Some lines are highly susceptible to cancer. Other lines are as highly resistant. The question is, how far are these mice from nature's own as regards cancer?

Drs. Howard B. Andervont and Thelma B. Dunn of the National Cancer Institute, Bethesda, Md., have been seeking the answer for 14 years. They now report that in nature cancer and mice are well acquainted, and apparently much better acquainted than cancer and people are.

Use House Mice

The scientists began in 1947 with 19 freshly captured house mice, 13 females and 6 males, relationships (if any) unknown. In 1951 they added 30 more unknowns from live traps, equally divided between the sexes.

These mice and their progeny then lived in cages for a sizeable part of the mouse life span. Overbreeding and any intensive inbreeding were prevented. Food, water and cage-cleaning were provided, of course. Otherwise science left them alone.

For a few years the mice which remained in health were permitted to live for two years before they were subjected to a post-mortem search for cancer. In laboratory mice that approximate the life span, but at two years the mice were flourishing still. Thereafter the mice were allowed to live for two years and six months.

Drs. Andervont and Dunn reported their autopsies of 225 mice of which 98 had a malignant tumor—or tumors. That's a percentage of 43.5, much higher than any of the various calculations or incidence of cancer among human beings.

Hits Older Mice

Of these mouse cancers, 64 per cent appeared in mice who were far past the prime of mouse life. Only one cancer appeared in a quite young mouse and the remaining tumors were spread out over mouse middle years. This has agreement with cancer and age in people.

Lung cancer was the most common cancer among wild mice. It was similar to lung cancer of inbred laboratory mice in which it also is common, but in the latter it usually occurs in multiples whereas in wild mice there was only a single tumor.

In inbred mice, lymphocytic leukemia also is common. There was only one case of it among the wild mice. In inbred mice it may be caused by a virus. The scientists wondered if inbreeding either increased the susceptibility of mice to the virus or the activity of the virus or both.

This question they couldn't answer at once, but another question they could and did answer. Viruses which cause the leukemia in inbred mice were injected into wild mice and caused leukemia in them, too.

HARD DAYS WORK

ST. LOUIS, Mo. (UPI)— Television news cameraman Jerry Kleiman went to film an exhibit at the Missouri Historical Society and ended up in the hospital.

Kleiman was filming gun collector John Boxdorfer's demonstration of an old muzzle loading rifle when the weapon accidentally discharged, severing an overhanging tree limb. A squirrel which had been watching the proceedings from the tree limb landed on Kleiman and bit and scratched him.

WHISTLE FIXER GONE

MENDOTA, Ill. (UPI) — This city is in the market for a new fire alarm whistle.

City fathers learned the last person who knew how to repair the old whistle no longer is around.
