Health Talks

SQUINT

Squint, or as it is technically known, strabismus, is a condition of much importance. Not only is it unsightly, but usually it points to one of several serious conditions. There may be a marked impairment in the vision of the squinting eye, or there may be some defect in the nerve mechanism controlling the eye.

The infant is not born with the capacity to focus his eyes. Hence, during the first six months of life squinting is natural and of no significance. Thereafter, however, any misposition (squinting) of the eyes is to be looked on with suspicion.

It is a good precaution for normal children to begin with normal eyes, and, say at the age of three, to develop a squint. Usually this follows an attack of measles, or whooping cough, and points to a weakening of the muscle nervous system of the eyes brought out by the illness.

Children with a squint may see double. Later on, even if the squint is not corrected, the double vision may disappear. But in the vast majority of cases, this does not mean a cure. On the contrary, it merely means that rather than see double, the child has learned to look through only one eye, the other picture being suppressed.

Because there is a tendency for the sight in the squinting eye to become progressively worse, it is important to begin treatment of the condition as soon as it is discovered. In many of the cases of so-called self-cured squint, the alleged cure was gained at the expense of the sight of one eye.

The younger the child, the easier it usually is to cure the condition.
