Northwest wine industry eyes UV light to treat powdery mildew

By **GEORGE PAVEN**
Capital Press

TURNER, Ore. — The robot shines an eerie green in the dark of night as it maneuvers over rows of grapevines at Willamette Valley Vineyards.

Developed by Norwegian-based Saga Robotics, Thorvald — as the system is named — is an autonomous, self-driving vehicle that looks a bit like a small shed on wheels. Inside, it is equipped with a special band of ultraviolet lights designed to suppress powdery mildew and other plant diseases.

As research continues to demonstrate the efficacy of UV light as a management tool for farmers, Willamette Valley Vineyards has become the first commercial operation to adopt Thorvald in place of traditional chemical fungicides to control powdery mildew in winegrapes.

“We see this as a remarkable opportunity for our industry to grow high quality winegrapes and do it in a very natural, sustainable way,” said Jim Bernau, the winery’s founder and CEO.

While Bernau and Willamette Valley Vineyards began experimenting with UV light last year, scientists from around the world have been conducting field trials on and off for decades, spanning a variety of crops including strawberries, apples, cucumbers and hops.

Today, a research team led by David Gadoury, plant pathologist at Cornell University, is gathering data and refin-

ing treatments using UV light, with results showing promise.

Gadoury was the featured speaker at a webinar May 27 hosted by Washington State University and the Washington State Wine Commission, providing vintners with the latest information about UV light and its potential as an alternative for curbing plant diseases.

Powdery mildew, in particular, is one of the most widespread problems in the wine industry. If not suppressed, the disease can reduce crop yield by as much as 95% and degrade wine quality.

The first field trials using UV light took place in 1991, though they were less than successful, Gadoury said. Though it effectively reduced powdery mildew in grapes, it also defoliated vines and

caused the fruit to shrivel, resembling miniature russet potatoes.

Then came a key discovery 10 years ago. A doctoral student in Norway found that UV light was much more effective killing powdery mildew at night, when the pathogens’ natural systems for repairing their DNA have shut down to conserve energy.

Not only are the pathogens more susceptible at night, but Gadoury said they were able to use 10% less UV-C to achieve the same levels of disease reduction, at levels that won’t cause damage to the plants or fruit.

“Pathogens such as powdery mildew, and many other organisms, just really don’t like UV light at night,” Gadoury said. “That means we can kill them with a fraction of the dose that’s required during daylight.”

New trials started in 2017 at a commercial strawberry farm in Florida. This time, they proved a rousing success, performing significantly better than applications of chemical fungicides.

Additional trials are now underway in places like California and Nova Scotia, Canada, as well as overseas in Europe.

“I think we’re beyond the point where we have to worry about whether or not this technology is going to provide sustainable control of strawberry powdery mildew,” Gadoury said. “It actually works quite well.”

OSU researchers find Southern Oregon winegrape growers can reduce water usage

By **SIERRA DAWN McCLAIN**
Capital Press

ROGUE VALLEY, Ore. — Winegrape growers in Southern Oregon may be able to slash water usage nearly in half while still producing high-quality, high-yield fruit, according to an Oregon State University study.

Many Southern Oregon growers consult water management data OSU researchers believe is either inaccurate or designed for a different region, leading some growers to irrigate too much.

“Watering twice as long as you need to is a big deal,” said Alexander Levin, the study’s leader and assistant professor and viticulturist at the Southern Oregon Research and Extension Center.

Overwatering, Levin said, costs more, hurts the environment, can leach nutrients from soil and wash fertilizer beyond roots. It can also create leafy canopies that attract pests and create dark, humid habitat for fungi. And in a drought, every drop of water is precious.

In Oregon, many growers use AgriMet, a free weather station sponsored by the U.S. Bureau of Reclamation, to determine how much water they need for specific crops.

The problem is AgriMet appears to overestimate how much to irrigate winegrapes by 44%.

AgriMet estimates winegrapes in the region need 20.2 inches of water per year. Levin’s study found winegrapes need only 11.4 inches annually to thrive.

That number — 11.4 inches — represents the ideal amount of water vines need to produce good-quality fruit and good yields. Winegrapes could survive with less water, such as 6 to 8 inches, but will perform better with around 11 inches.

Along with using AgriMet, some growers also use crop coefficients — properties of plants used to predict evapotranspiration for irrigation scheduling — that were developed in California, where crop growth, water requirements, latitude and weather patterns differ.

By using OSU’s numbers, Levin estimates Southern Oregon growers can conserve 11% of their water compared to using California numbers.

Levin said his findings may even impact growers who already practice “deficit irrigating” — applying less water than is required for a crop. That’s because, Levin said, even some deficit

irrigators may be irrigating too much.

A “deficit irrigator” watering 25% less than AgriMet’s suggested 20.2 inches, for example, is still applying 15.5 inches per year, above OSU’s suggested 11.4 inches.

Levin arrived at his 11.4-inch “ideal” by conducting research at vineyards in Jackson County starting in 2017. He used solar panels to estimate vines’ evapotranspiration and to find the “crop coefficient,” which can be plugged into a mathematical equation for irrigation adjustments.

AgriMet staff have not yet confirmed, either to Levin or the Capital Press, whether they plan to use Levin’s findings at the weather station. In the meantime, Levin encourages growers to email him at alexander.levin@oregonstate.edu for the new crop coefficient.

Michael Moore, general manager at Quail Run Vineyards and one of the growers who participated in Levin’s trials, said he thinks Levin’s numbers are accurate.

Moore irrigates his winegrapes about 12 inches annually, which he said “feels really appropriate for our area.”

Although Levin’s study will likely prove useful in the future, it may have little impact this year, because growers would be lucky to have 11.4 inches of water. Some water districts are telling growers just to fight for vine survival.

“The scope of the drought going on right now is monumental,” said Moore.
