How Movies Work

Liberty Theater operator tests system of projection.

The Liberty Theatre operator is testing a new method of projection at his theatre that promises to revolutionize the entire system of presenting motion pictures. The new system is based on the principle of projecting the screen with a single, continuous strip of film instead of the usual intermittent method of projecting two or more separate strips of film. The single strip of film is fed continuously from a supply reel to a take-up reel, and the projector is designed to maintain a constant speed of projection. The new system offers several advantages over the old intermittent method, including a smoother, more realistic image, a quieter operation, and a more uniform sound track. The Liberty Theatre operator is expected to begin using the new system within the next few weeks, and other theaters are expected to follow suit.
