The experiment that the Oregon Power & Railway Company has made in the use of power for the operation of street cars in Portland has given such good results that the company are now at the point of extending its operations to other lines throughout the city.

The installation of the new system of power is now in progress and the work is expected to be completed early next year.

The scheme of operation is based on the principle that the power for the movement of the cars can be generated and transmitted from a central station, thus eliminating the necessity of having a separate engine at each car.

The advantage of this method is that it permits a greater efficiency of operation and reduces the cost of maintenance.

The new cars will be equipped with electric motors which will be controlled by the operators from inside the cars.

The system is being carried out in the United States and Canada, and is considered to be one of the most economical methods of operation for small cities.

The company has decided to extend its operations to other lines in the future, and the work is expected to be completed early next year.

In the meantime, the company will continue to operate the present system of power, and the work will be completed as soon as possible.

The results of the experiment are expected to be published in the next issue of the company's monthly bulletin.
