Oregon Third In Peppermint Production

Oil Harvested From 4500 Acres in Oregon Last Year Says Report By LILLIE L. MADSEN

Garden and Farm Editor Commercial peppermint oil production in the United States was not important until 1900. From then until 1925, Michigan and Indiana, but especially Michigan, produced three-fourths of the world's peppermint oil. During the past few years, Oregon has ranked third highest in production.

In 1943, Oregon harvested oil from 4500 acres. Plantings for 1944 harvest, are said to have been increased 18 per cent over the 1943 plantings. Large plantings have been made for a number of years in Columbia county along the Columbia river. Linn and Lane counties have quite some acreages.

Considerable peppermint was grown in Labish section a few years ago. Now, only small plantings are left there, with Willamette valley plantings now centering in a new community along the Santiam.

According to W. G. Nibler, Marion county agent, approximately 800 Marion county acres are now planted to peppermint. We are unable to obtain exact figures from O. E. Mikesell's Linn county office, but indications were that Linn county office, but indications were that Linn county had a similar acreage to that of Marion's. In both counties plantings center on the Santiam bottom land not far from Jefferson. This section, then, produces approximately one third of Oregon's large mint oil crop.

Trip Into Peppermint Section

With this information in hand, we made a trip to the peppermint section known as Dever in Linn county, and Talbot in Marion.

Loose sandy soil and plenty of water, we found, were essentials to good mint production. We also learned that it costs approximately \$25 to plant an acre of mint, and that sufficient roots can be harvested from one acre to plant an acre of mint, and that suffi-

man reporters found that there were an additional 21 acres of mustard scattered over the 400 acre farm yet to be harvested (Statesman staff photo)

Farmers are letting their veal European countries for livestock to grow on a scant ration just as it are known to have objectionable calves run with the cows. The from United States farms is un- is impossible for dairy cows to calves fattened earlier and both milking and calf feeding are done try. Dr. Reed points out that after an increase in milk flow when away with in a season when there is plenty to do besides chores.

Raising Calf Found to Be Important

The cost of raising a calf from birth to first freshening at about 25 months of age ranges between \$70 and \$125, depending largely on the prices of feed and labor. About one-half of this represents feed cost. About 10 per cent of the cost of raising calves represents losses on heifers that die after having expended on them a considerable investment in feed and other cost items. This loss can be reduced by careful feeding and management. The price received on the average for heifers sold is 10 per cent below the cost of raising them. The importance of calfraising on Oregon dairy farms is indicated by the annual expenditure of about \$6,000,000 in bringing them to maturity.

Too often the purchased cow is a poor producer, short-time milker, slow breeder, or has a chronic udder infection. It is the safest and, over a period of years, the dairyman to plan on raising the number of heifer calves necessary to maintain or to increase the size of his milking herd. The good dairyman, therefore, should consider the job of raising calves as important and necessary, if he is

Vegetables to **BePlanted** Now

A number of important veget bles arrive at the peak of their development during the fall months. These crops include various members of the cabbage family such as cabbage, cauliflower, broccoll, Brussels sprouts, and curly kale, A. G. B. Bouquet tells us. He adds that other crops such as celery, lettuce, spinach, root crops of various kinds, Swiss chard, mustard, late corn and beans also thrive in the cool, crisp, moist days of fall. Many of these crops reach their finest edible quality at that time.

It is important that the gardener realize the value of these late season crops and include them in the gardening program.

Lettuce is an important fall vegetable and can be grown from seed in 75 to 90 days, depending upon the type of lettuce grown and the temperatures prevailing. Fall lettuce should be started in August. Seed should be dropped thinly in rows 24 inches apart and the plants later thinned to stand 12 to 14 inches if head lettuce is grown. Lettuce heads are quite subject to injury when frosty weather occurs.

Spinach is a hardy and guick growing crop and under favorable temperatures can be grown in about 6 to 7 weeks. The seed should be planted in August or the very early part of September. Rows of spinach are usually about 18 to 24 inches apart. No thinning of the plants is required. A sidedressing of nitrate of soda or sulphate of ammonia may be applied alongside the rows during the early fall rains-if these can be had.

Fall-grown radishes usually are free from maggots. Radishes can be planted at various intervals up to October 15. There is a large range of varieties varying in color and shape.

Seedings #f turnips can be made either broadcast or in rows. Later plantings usually escape maggot injury. If broadcasting the seed, the land should be clean of weeds. There are three types of varieties that may be grown, white, yellow and purple and white.

If table rutabagas are grown, the rows should be far enough apart for cultivation and the plants thinned to about 6 inches of mill by-products; ground grains; apart in the row. Both turnips high protein concentrates such as and rutabagas may be planted from August 13

to make the greatest success of the dairy herd enterprise. The main consideration in se-

lecting the heifer to raise should be given to the possibilities and probabilities of her inheriting good milk and butterfat producing ability from her parents, according to L R. Jones of Corvallis. It costs just as much to raise a heifer without inherited genes for high production. The calves selected for raising should be from the best producing and transmitting cows in the herd. The best cow families in the herd can easily be determined by actual records of production for several generations. The need for raising only heifer calves sired by a good dairy bull should be emphasized. If the bull

Small Profit

Large Amounts Made on Eggs by Only Relatively Few Producers

Only a relatively small profit per dozen is made from the production of eggs for the market. And this is made only by a few efficient poultrymen. This does not mean that only poultrymen with huge profits make profits, but it does mean that a great many people who keep chickens for egg production do so at a loss.

Feed represents the largest item of cost in the business of producing eggs. Until experience hydrates and fats in relatively warrants, the producer will have large amounts but do not contain better success by accepting proved a large supply of either proteins

feed combinations and adhering or minerals. Grains alone do not closely to some definite, approved constitute a balanced ration for method of feeding, rather than by egg production. To supply the deexperimenting with feeds on his ficiency the grain feeds must be supplemented by a mash composed

Fire Equipment May stock. Priority will no doubt be Vary Feed **Be** Needed in Field

The minimum.essentials for any farmer for his part in fire-fighting equipment are a supply of water, gunny sacks, shovels, fiails, and pump cans ready for immediate

use. Some of these can be kept on the tractor and combine at all

times. A well placed plow is also one of the most important pieces of fire-fighting equipment. ' If a fire starts and gets beyond

the size where it can be handled immediately with water, shovels, sacks, the plaw is put into action.

Dan E. Robinson, of the Oregon state board of forestry, says that experience has shown that the best way is to begin plowing a line parallel to the direction the fire is travelling, starting on the down-wind flank of the fire, gradually working toward the head of the blaze. It is always best to turn the furrow toward the fire. A ground

crew following with hand tools is essential. The inexperienced fire fighter is likely to turn in front of the blaze too soon and may be forced to slightly less effective than the
