Cream Story

(Continued From Page One)

been adjusted to yield a desired richness of cream, it should not be changed.

2. Speed of the separator. When the speed of the separator is increased above normal the cream will test higher, and when the speed of the separator is decreased below normal the cream will test lower. A decreased speed results in a loss of fat in the skim milk. Irregularity in the speed of the machine is probably the greatest factor in causing cream

test variations. Usually different individuals operate the separator with the result that the speed is neither uniform nor constant. A timing device should be employed to check the speed. When the separator is factory equipped with an electric motor, the pulleys and gearing are designed to give the proper speed at the designated electric current. Should the electric current be too high or too low the speed of the separator will be increased or decreased, and the fat test of the cream will vary accordingly. In equipping the separator with motor power, be sure the pulleys are of proper diameter to insure proper bowl speed. Best results are obtained when the separator operates smoothly and steadily at the speed designated by the manufacturer.

3. Rate of inflow. The inflow of milk is regulated by a float which permits the proper amount of milk to enter the bowl only when the faucet is wide open. Overfeeding the separator, by removing the float, results in inefficient separation and a thinner cream. Underfeeding, by partly closing the faucet, yields a richer cream.

The faucet of the milk tank should be centered above the bowl so that the float may regulate the flow of milk into the bowl without hindrance. Always use the float and always have the faucet wide open when the separator is in operation.

4. Unclean separator. When the separator bowl is dirty the flow of milk is retarded. Some of the openings between the discs become clogged so that more skim milk flows through the cream outlet. A clogged separator bowl always delivers a thinner cream. The quality of the cream is lowered also. Wash and dry thoroughly all the separator parts after each separation.

5. Vibration of Separator. When the bowl vibrates while the milk is being separated, there occurs a remixing of the cream and skim milk in the bowl, which results in inefficient skimming and a thinner cream. A vibrating bowl is often caused by starting the separator too quickly, by the separator not setting level, by water in the oil, or by worn bushings. Always start the separator slowly, applying the power gradually. Keep the machine well oiled with a good separator oil and have the machine level so the bowl balance will be maintained.

6. Amount of Flush Water. The greater amount of water or skim milk used to flush the bowl, the thinner will be the cream. The flushing of the bowl itself is of as largely responsible for a wide variation in the cream as the practice of allowing the watery discharge to flow into the cream. Flush the bowl gradually by using the same amount of warm water or skim milk after each separation.—Michigan Extension Service (To be Continued.)

The holidays are over

Gone their parties, their decorations and the long evenings of play for young and old.

Consider how unobtrusively, yet how greatly electricity has contributed to the color, the comfort and the safety of your holidays.

Christmas decorations safely illuminated—plenty of light for entertaining or for reading those new books.

Certainly your electric bill may be a trifle larger—but consider how small the additional expense compared to the brightness and joy it brought.

Without this inexpensive service holidays would indeed be drab.
