Is That So?

By EUGENE BURNS
Ranger-Naturalist

Knowing "which way is up" is a much more complicated operation than most of us realize. For example, how does a floating fish in the intense darkness of the ocean deep know this? Or man, when confined within a light-sealed tilted room?

The answer to this balance like within the tiny inner ear.

It's like this. All animals with a backbone—from the shark, lowest of these vertebrates, to man, the highest—have set of semi-circular canals in the head partly filled with a watery liquid.

In these liquid-filled canals are tiny hairs which bend easily in the direction the liquid flows when the head is tilted. To the base of these hairs are attached tiny nerves which tie in with the eighth of the 10 or 12 major nerves all animals have in their heads, and this large nerve leads directly to the brain.

Now then, when the head is tilted, the fluid within these three semicircular canals in the inner ear flows in that direction, bending the hairs, and quick as a flash the nerve ends hurry the information of unbalance to the brain where appropriate action is taken.

Should a person make several rapid turns, going 'round and 'round, the fluid within the canals would tend to keep going—just as it would in turning a bucket of water—and thus these tiny hair cells would continue to be stimulated and keep the person off-balance. In short, dizzy.
