TOSS BOMBING, a new bombing technique developed by the U.S. Air Force, is shown in this photograph of an F-100 jet fighter-bomber as demonstrated at the Aerial Firepower Demonstration held October 7, at Eglin Air Force Base, Florida. Smoke flares were attached to both the aircraft and the bomb so the spectators at the show could observe their paths. Toss bombing is designed to allow the aircraft to drop a comparatively small tactical atomic bomb and then escape the blast. Official USAF photo.

Electron Microscope Sets Light On Nerve System

ST. LOUIS, Mo. — The powerful electron microscope has thrown new light on construction of the nervous system — knowledge that could eventually help solve the mystery of multiple sclerosis and similar diseases.

The discovery concerns a substance known as myelin, found in the protective coating around nerves in the brain and spinal cord. Myelin is attacked and destroyed by degenerative diseases of the nervous system.

Dr. Sarah A. Luse, assistant professor of pathology at the Washington University Medical School, reporting on a two-year study, said it revealed myelin in the central nervous system actually is formed by and is a part of the nerve-protecting cells.

Until recent years myelin was regarded as inert matter of unknown origin deposited around the nerves.

Dr. Edward W. Dempsey, head of the anatomy department at the school and a member of the research review panel of the National Multiple Sclerosis Society, explained the significance of Dr. Luse's findings.

"The information on the origin and nature of myelin is a first-rate scientific discovery, not necessarily because of its relation to any disease, but because of the light it throws on the way the nervous system is constructed," Dr. Dempsey said.

"Every piece of information adds one more clue which finally could be used in unraveling the entire progress of multiple sclerosis and similar diseases of the central nervous system."
